

Seeing Through the Clouds of Venus

Giada Arney

ESS 495

5/2/13

Sister Planets?

Similar size (95%), mass (82%) and density (95%)

Venus is a terrible place

96% CO₂

3.5% N₂

T_s = 740K = 872°F

P_s = 93 atm

H₂SO₄ clouds

78% N₂

21% O₂

T_s = 288K

P_s = 1 atm

H₂O clouds

The Greenhouse Effect

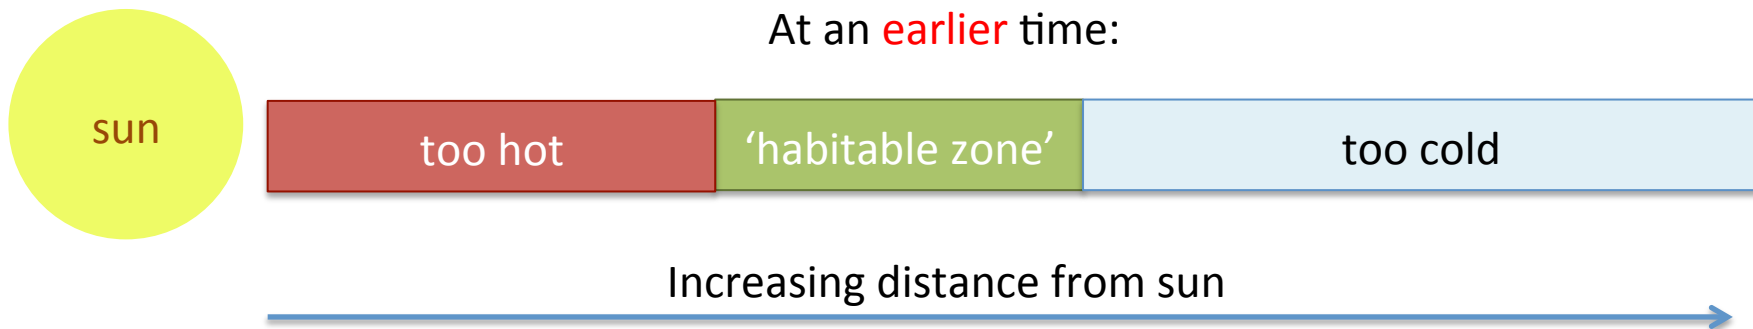

The image features two spherical celestial bodies against a black background. The body on the left is smooth and has a pale yellowish-tan hue. The body on the right is larger, more prominent, and covered in numerous brown and tan spots and lines, representing a heavily cratered and eroded surface. The text 'How Did Venus End Up Like this?' is centered over the two bodies in a white, sans-serif font.

How Did Venus End Up Like this?

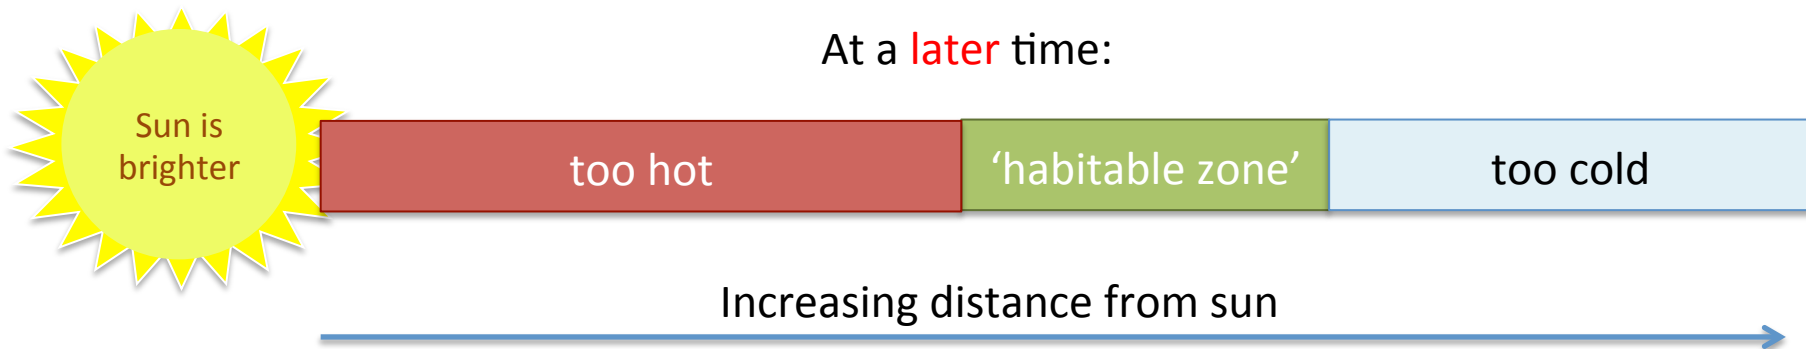

A couple of things to know...

- The sun gets ~6% more luminous every 1 billion years
- As the sun gets brighter (hotter) with time, the region around the star where habitable planetary temperatures are possible gets pushed outward

A couple of things to know...

- The sun gets ~6% more luminous every 1 billion years
- As the sun gets brighter (hotter) with time, the region around the star where habitable planetary temperatures are possible gets pushed outward

So...

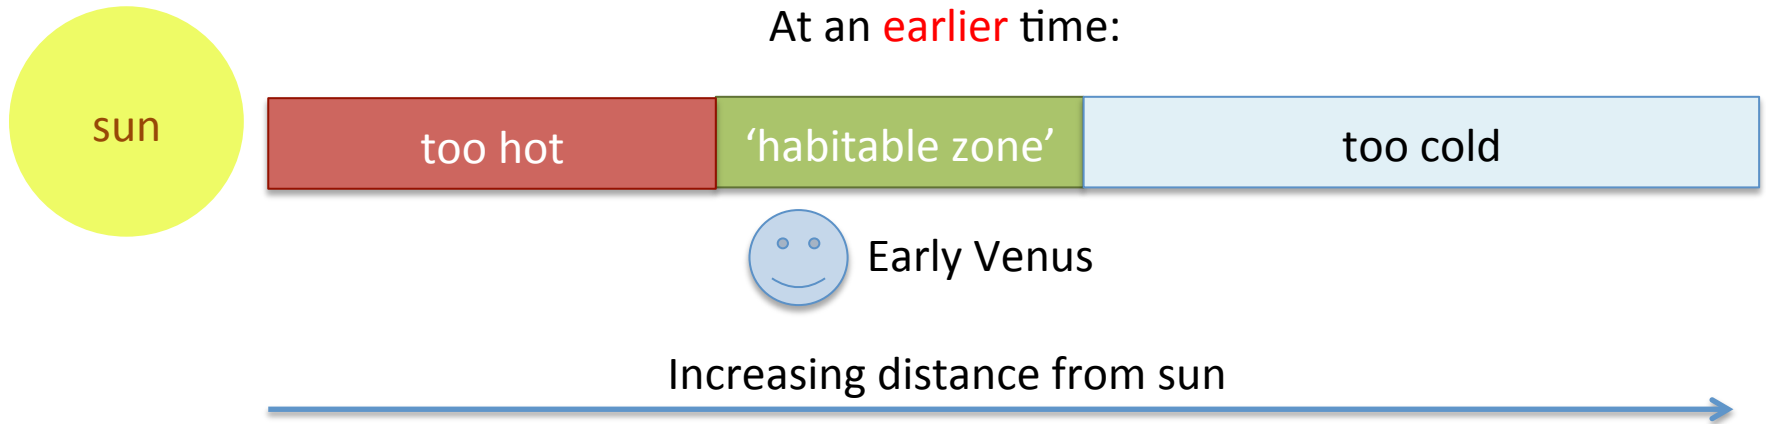

- The heat received by a planet from the sun continually increases with time.
- The 'habitable zone' moves farther away from the star with time.
- A planet that was once in the habitable zone at one time may become too hot later

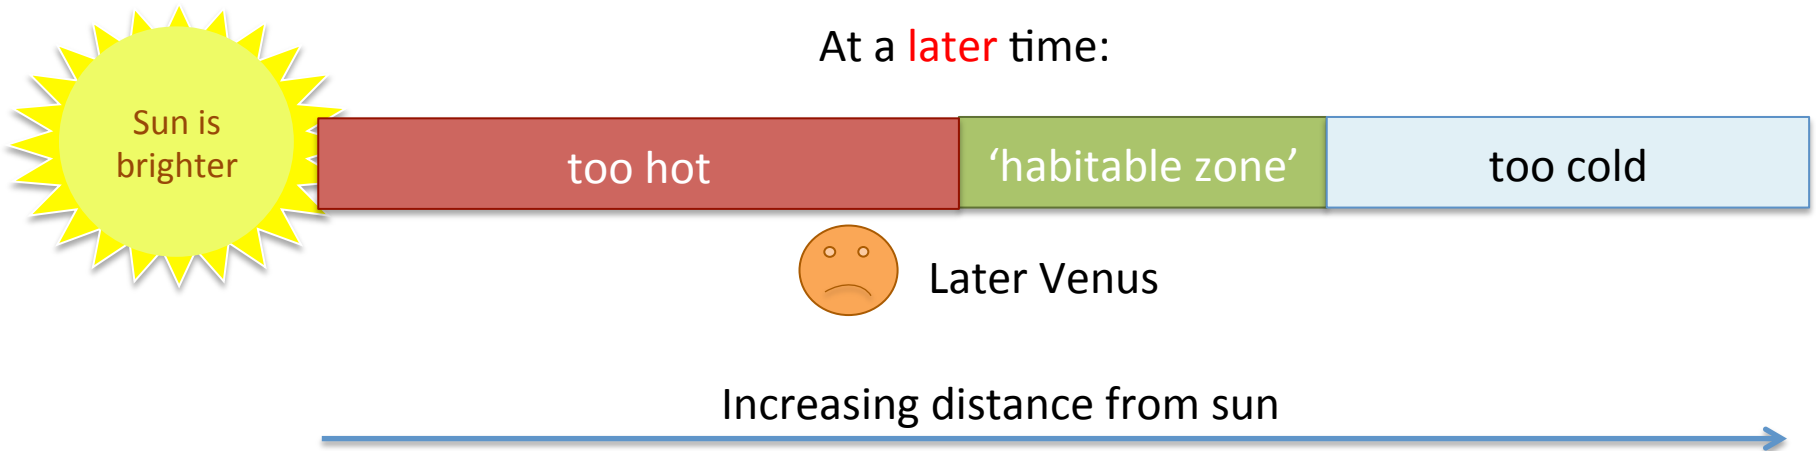

This may have happened to Venus

The Fate of Venus

At an **earlier** time:

At a **later** time:

The Fate of Earth?

Today:

At a **later** time:

Exoplanet population

- Are Venus-like planets common?
 - The migration of the habitable zone outward may leave Venuses in its wake
 - There may be large number of Venus-like worlds in the exoplanet population
 - “end state” of Earthlike planets?

Mercury

Venus

Earth

Mars

Jupiter

The image features two planets against a solid black background. In the foreground, a planet with a bright yellowish-orange, heavily cratered surface is shown, representing Venus. Behind it and to the left is a larger, pale yellow planet with distinct horizontal cloud bands, representing Jupiter. The text 'Observing Venus' is centered over the image in a white, sans-serif font.

Observing Venus

We need to talk...about **light**

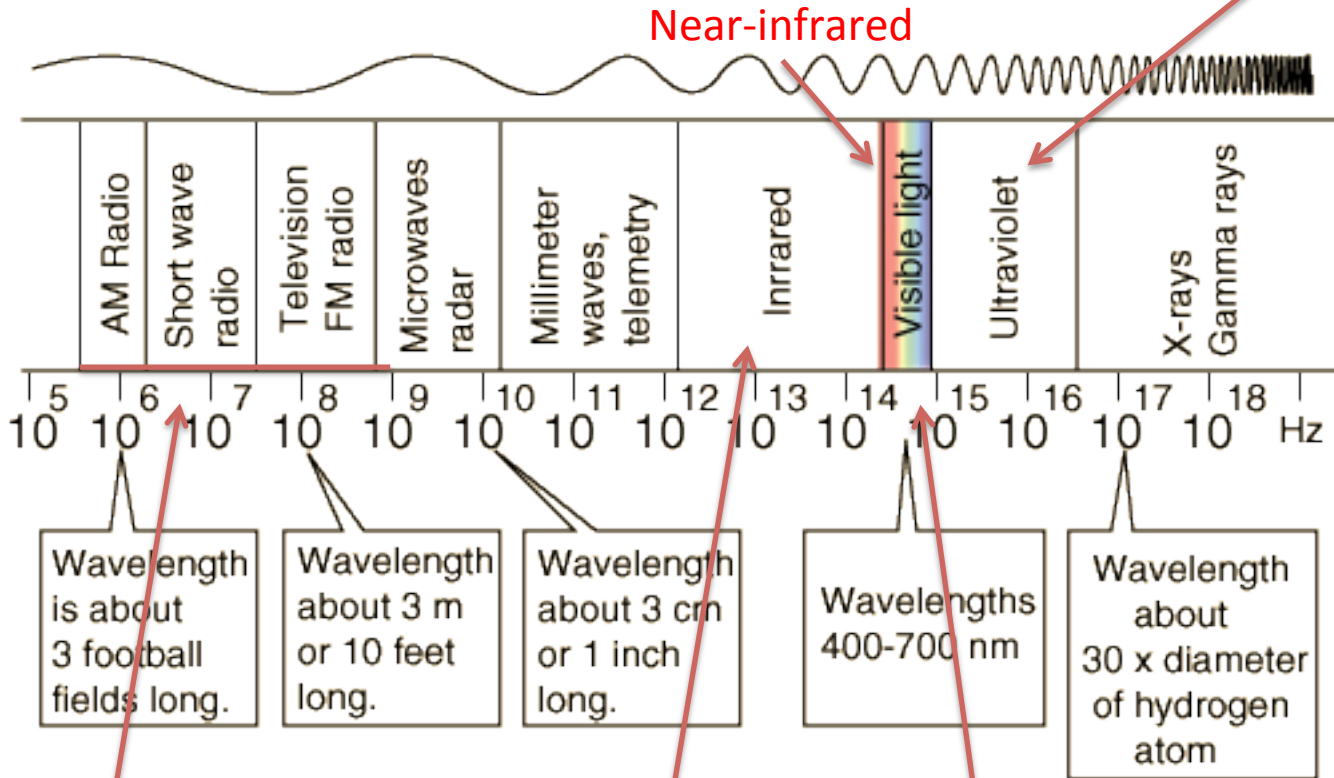

- Think of light “particles” (aka photons) as little wave packets of oscillating electric + magnetic fields traveling through space

Different “wavelengths” = different types of light

Spectrum of Light

Gives you sunburns ☹️

Near-infrared

Infrared

Visible light

Ultraviolet

X-rays
Gamma rays

10⁵ 10⁶ 10⁷ 10⁸ 10⁹ 10¹⁰ 10¹¹ 10¹² 10¹³ 10¹⁴ 10¹⁵ 10¹⁶ 10¹⁷ 10¹⁸ Hz

Wavelength is about 3 football fields long.

Wavelength about 3 m or 10 feet long.

Wavelength about 3 cm or 1 inch long.

Wavelengths 400-700 nm

Wavelength about 30 x diameter of hydrogen atom

Your body feels infrared wavelengths as heat

These wavelengths register in your eyes and brains as different colors

Used for broadcasting & communication

Spectroscopy

- Spectroscopy studies interactions between light and matter
- Different atoms and molecules emit and absorb light at different characteristic wavelengths

Hydrogen Absorption Spectrum

Hydrogen absorbs these wavelengths of light, so they cannot be seen in the spectrum

Spectroscopy is useful!!

Planet

Telescope + spectrograph

Hydrogen Absorption Spectrum

If you see hydrogen there, then you can say...

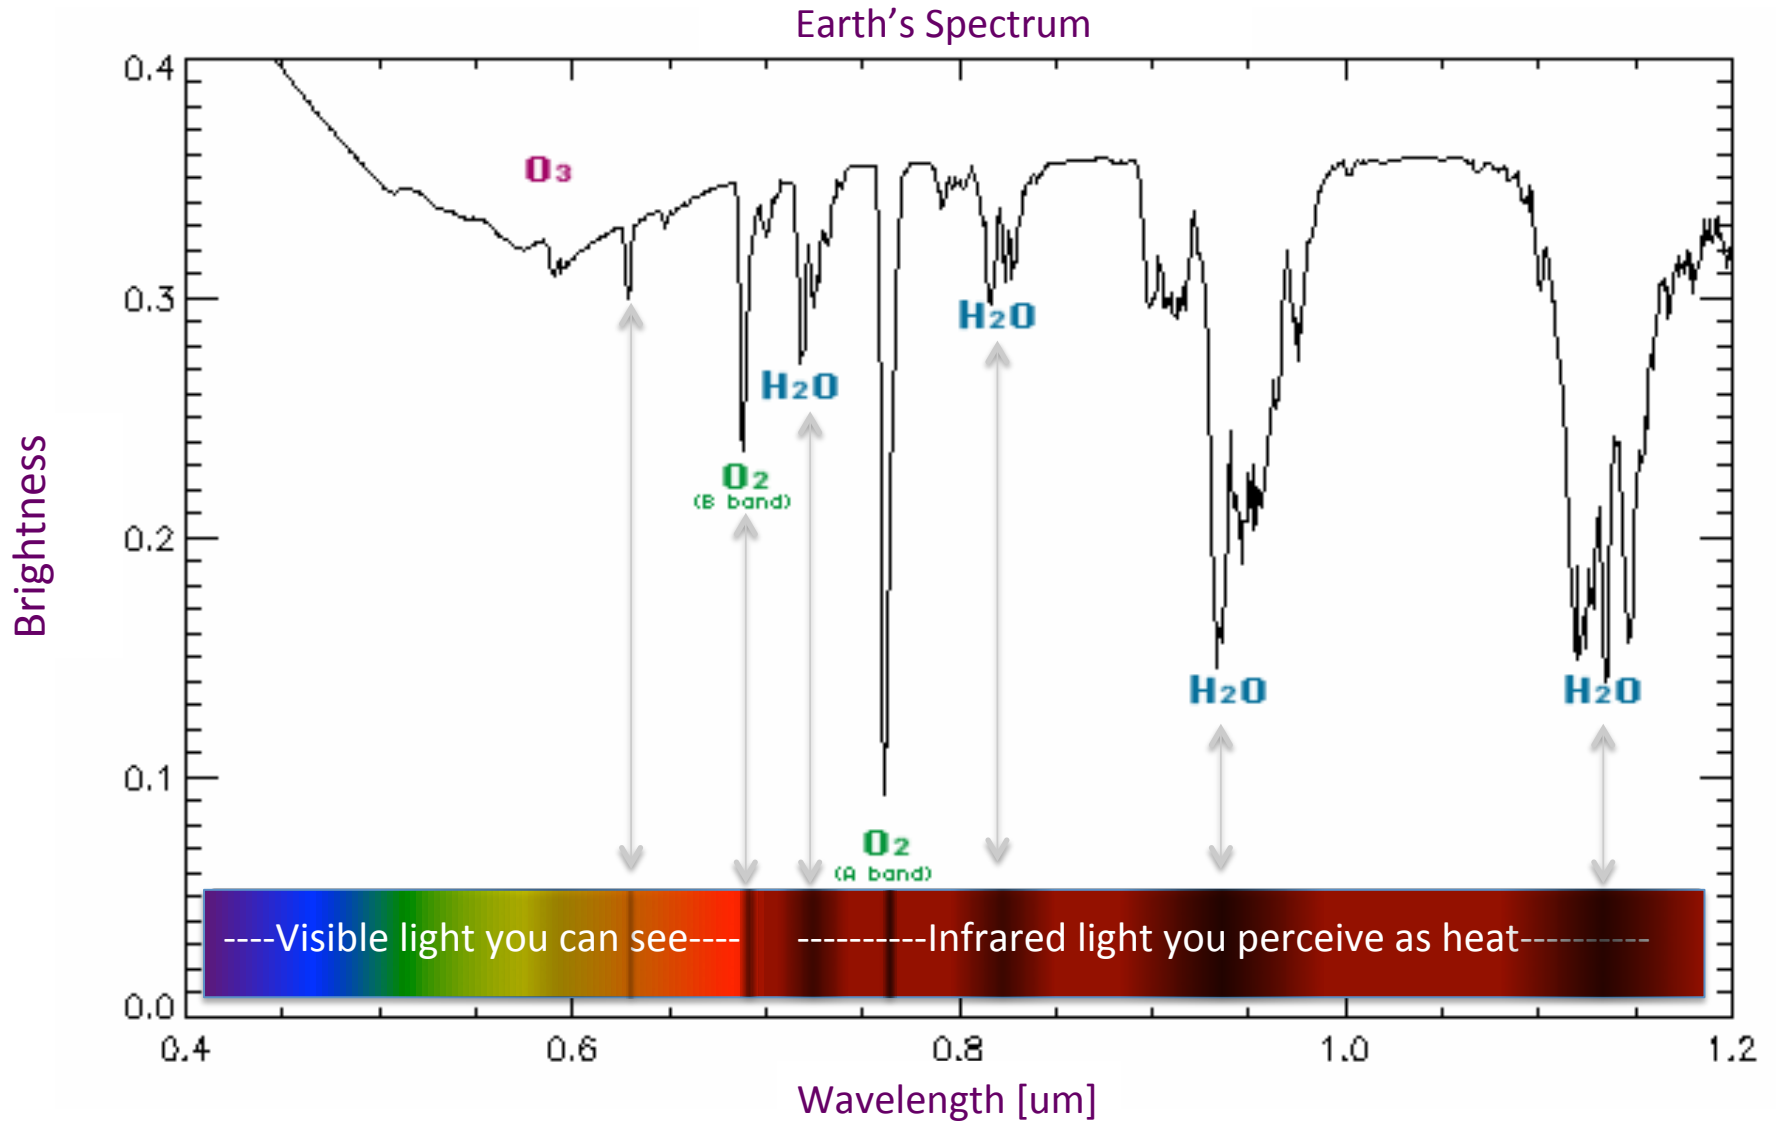

(basically a complicated prism)

Aha! This planet has hydrogen in its atmosphere!

Example spectrum

crescent moon

crescent Venus

Superior conjunction

"pre-conjunction"

"post-conjunction"

Inferior conjunction

Our observations

- Six nights in late November & early December 2010
“post-conjunction”
- Apache Point Observatory 3.5m telescope Triple Spec instrument

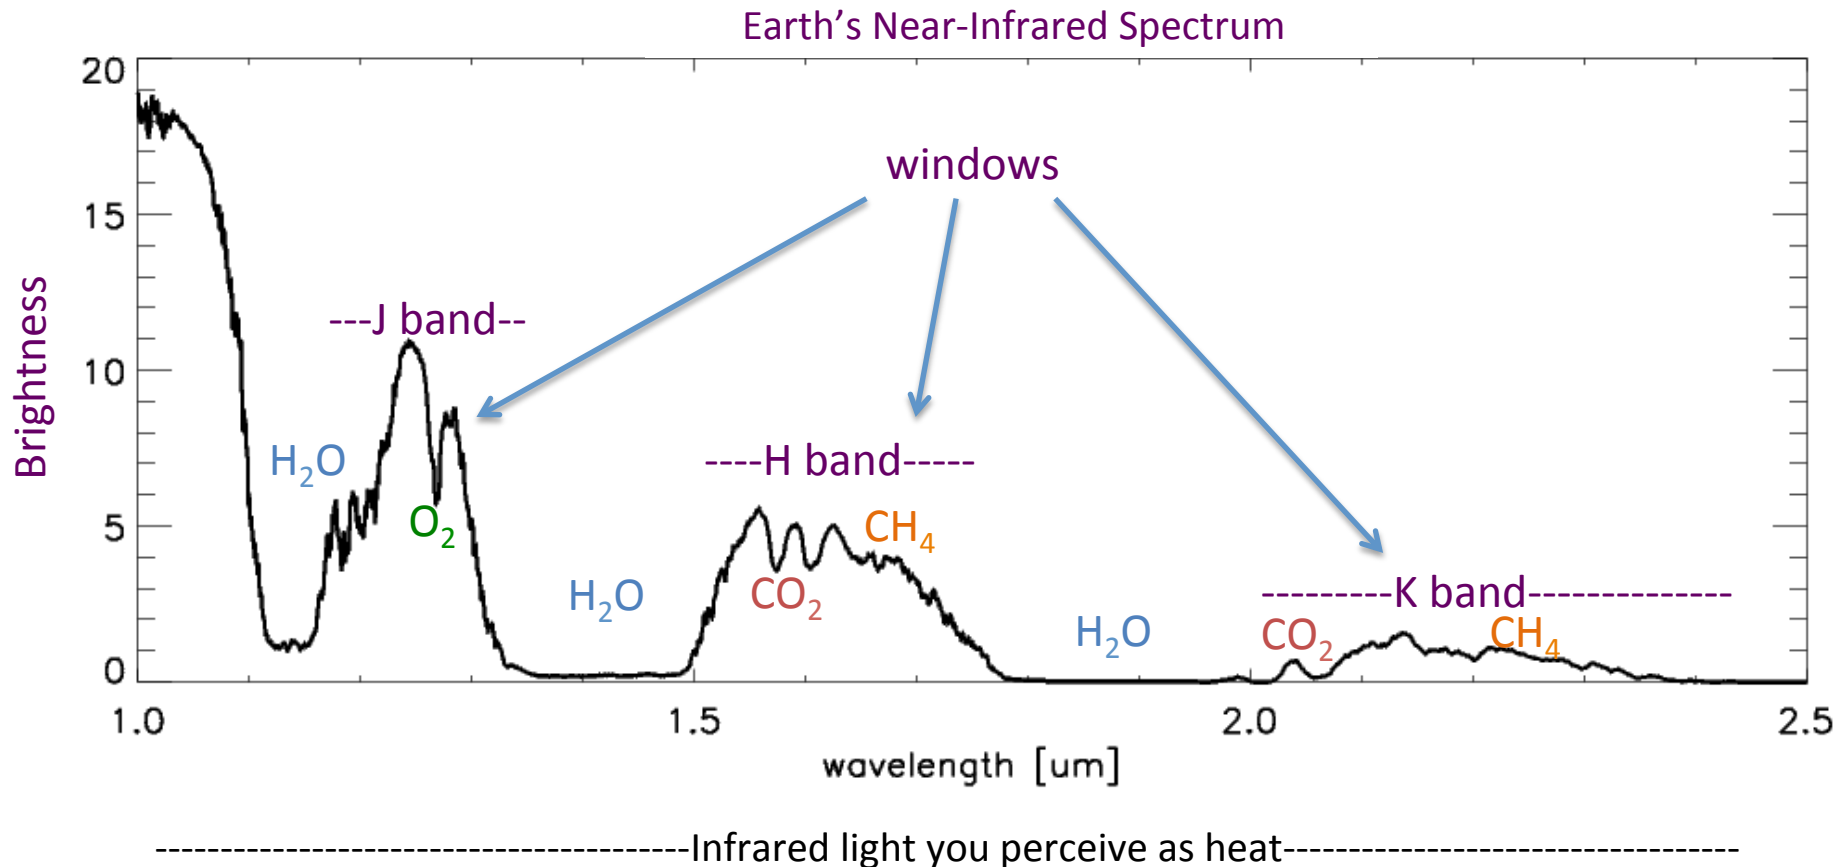

Why are we doing this?

- What do we want to learn?
 - What's in Venus' atmosphere and where is it?
This will help us better understand the Venus greenhouse
 - Is there current volcanism?
- How can we learn these things?
 - Spectroscopy of Venus' atmosphere
 - Imaging the surface of Venus

Near Infrared Atmospheric Windows

Earth's atmospheric windows: J, H, K bands
This spectrum is of Earth's DAYSIDE

Near IR Atmospheric Windows

Think of windows as places where the atmosphere is relatively transparent.

- Good wavelength regions to look into space if you're on the surface (or to look at the planet's surface if you're in space).

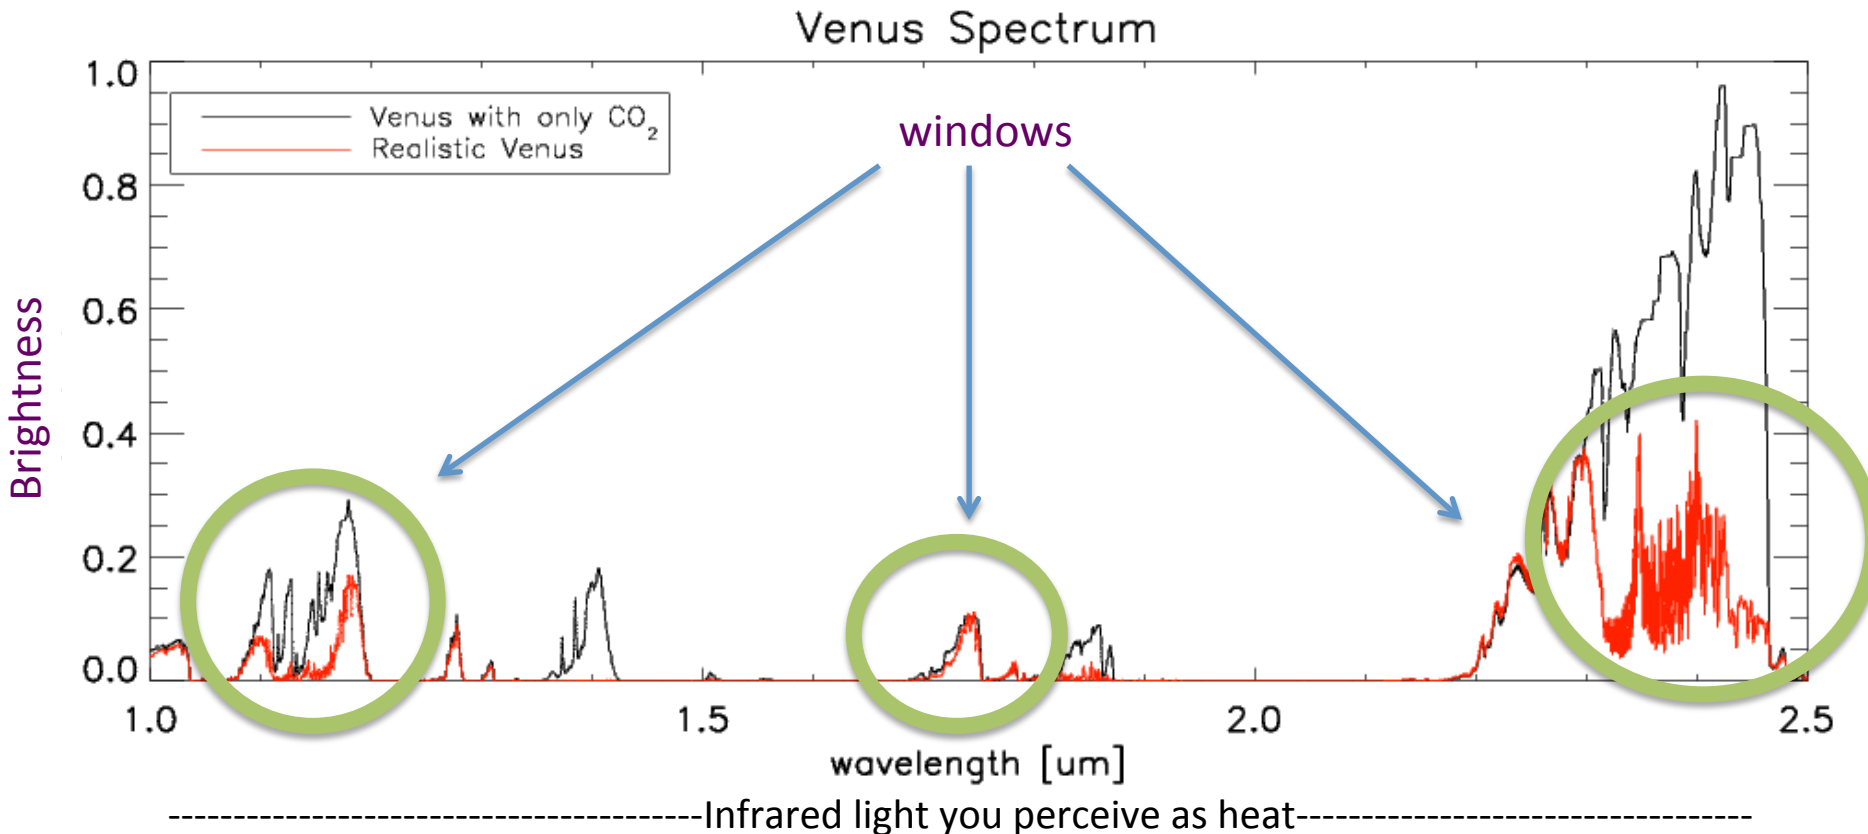

Earth's NIR atmospheric transparency

Near IR Atmospheric Windows

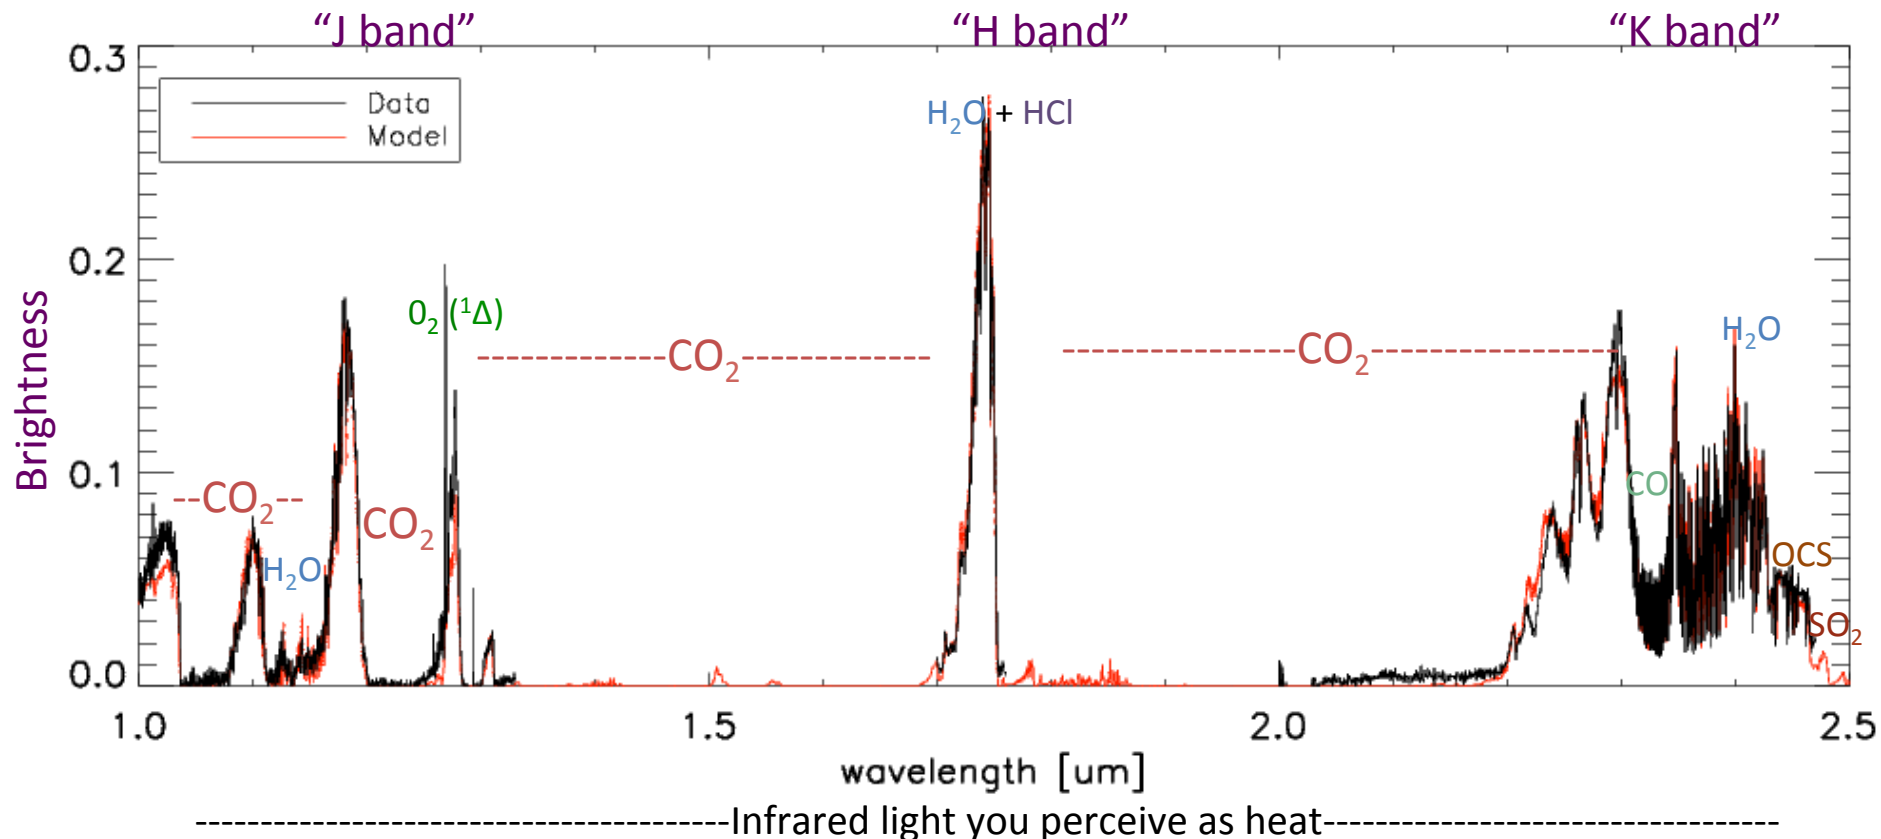

We can use Venus' atmospheric windows to probe the surface and lower atmosphere.

These spectra are of Venus' NIGHTSIDE

Near IR Atmospheric Windows

Venus atmospheric windows can measure minor species, can tell us about cloud properties, and can measure surface thermal variations

The data we have

- 6 nights of data

Each pixel has an associated 1-2.5 μm spectrum

Spatial, temporal, and spectral information

Imaging the surface

1.0um window is 96% surface thermal emission

Dayside crescent Nightside we observed

Imaging the surface

How do you do it?

Measure 1 μ m brightness in each pixel

Build up map of brightness variations

Aphrodite Terra

Images in the Windows

1.31 microns

1.10 microns

1.28 microns

1.00 microns

1.18 microns

Surface Elevation

The windows probe to different altitudes, so we see different patterns at different wavelengths.

Beta Regio

Oxygen Airglow

- CO₂ is broken apart high in the atmosphere on the dayside. O₂ recombines in mesosphere on the nightside and releases light at ~1.27μm

AAT IRIS Data, 1993, Meadows, Allen and Crisp

Measuring Atmospheric Species

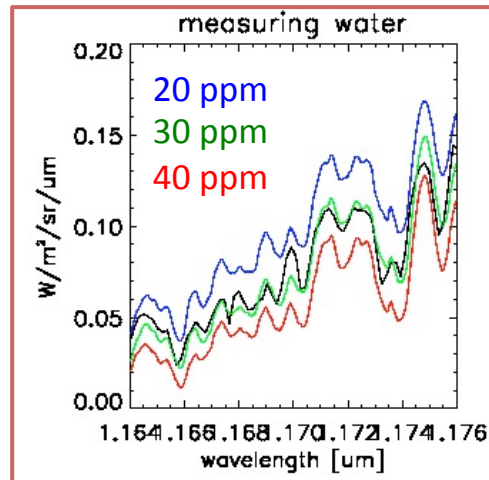

The general idea is:

Measure spectral range of interest in each in each pixel

Compare models to data in spectral region

Determine best fit model for each pixel to build up abundance maps on each night
